

## Generalized Ridge regression

Consider the regression model

$$Y = X\beta_* + \varepsilon,$$

where  $X \in \mathbb{R}^{n \times d}$ ,  $\beta_*$  is an unknown vector in  $\mathbb{R}^d$  and  $\varepsilon \sim \mathcal{N}(0, \sigma^2 I_n)$ . Define the generalized Ridge estimator by:

$$\hat{\beta} \in \operatorname{Argmin}_{\beta \in \mathbb{R}^d} \{ (Y - X\beta)^\top W (Y - X\beta) + (\beta - \beta_0)^\top \Delta (\beta - \beta_0) \},$$

where  $\beta_0 \in \mathbb{R}^d$ ,  $W \in \mathbb{R}^{n \times n}$  is a diagonal matrix with elements in  $[0, 1]$ ,  $\Delta \in \mathbb{R}^{d \times d}$  is a definite-positive matrix.

1. Provide the expression of  $\hat{\beta}$  when  $\beta_0 = 0$ ,  $W = I_n$  and  $\Delta = \lambda I_d$  where  $\lambda > 0$ .

*Proof in lecture notes.*

2. Solve the optimization problem in the general case.

For all  $\beta \in \mathbb{R}^d$ , write

$$\mathcal{L}(\beta) = (Y - X\beta)^\top W (Y - X\beta) + (\beta - \beta_0)^\top \Delta (\beta - \beta_0).$$

Therefore, for all  $\beta \in \mathbb{R}^d$ ,

$$\nabla \mathcal{L}(\beta) = 2 \left( (X^\top W X + \Delta) \beta - \Delta \beta_0 - X^\top W Y \right).$$

Note that  $X^\top W X + \Delta$  is definite-positive so that  $\nabla \mathcal{L}(\beta) = 0$  has a unique solution given by

$$\hat{\beta} = (X^\top W X + \Delta)^{-1} (\Delta \beta_0 + X^\top W Y).$$

3. Compute  $\mathbb{E}[\hat{\beta}]$  and show that the estimator is unbiased when  $\beta_0 = \beta_*$ .

Assuming that the design is not random,

$$\mathbb{E}[\hat{\beta}] = (X^\top W X + \Delta)^{-1} (\Delta \beta_0 + X^\top W \mathbb{E}[Y]).$$

This yields

$$\mathbb{E}[\hat{\beta}] = (X^\top W X + \Delta)^{-1} (\Delta \beta_0 + X^\top W X \beta_*).$$

In the case where  $\beta_0 = \beta_*$ ,

$$\mathbb{E}[\hat{\beta}] = (X^\top W X + \Delta)^{-1} (X^\top W X + \Delta) \beta_* = \beta_*$$

and the estimator is unbiased.

4. Compute  $\mathbb{V}[\hat{\beta}]$  and the mean squared error  $\mathbb{E}[\|\hat{\beta} - \beta_*\|_2^2]$  when  $\beta_0 = \beta_*$ .

By definition of  $\hat{\beta}$ ,

$$\begin{aligned} \mathbb{V}[\hat{\beta}] &= (X^\top W X + \Delta)^{-1} X^\top W \mathbb{V}[Y] W^\top X (X^\top W X + \Delta)^{-1} \\ &= \sigma^2 (X^\top W X + \Delta)^{-1} X^\top W W^\top X (X^\top W X + \Delta)^{-1} \\ &= \sigma^2 (X^\top W X + \Delta)^{-1} X^\top W^2 X (X^\top W X + \Delta)^{-1}. \end{aligned}$$

If  $\beta_0 = \beta_*$ , as the estimator is unbiased,

$$\begin{aligned}\mathbb{E}[\|\hat{\beta} - \beta_*\|_2^2] &= \text{Trace} \left( \mathbb{V}[\hat{\beta}] \right) \\ &= \sigma^2 \text{Trace} \left( (X^\top W X + \Delta)^{-1} X^\top W^2 X (X^\top W X + \Delta)^{-1} \right) \\ &= \sigma^2 \text{Trace} \left( X^\top W^2 X (X^\top W X + \Delta)^{-2} \right) .\end{aligned}$$

5. Assume that  $W = I_n$ ,  $\beta_0 = 0$  and  $\Delta = V\Lambda V^\top$  where  $X = UDV^\top$  is a singular value decomposition of  $X$  and  $\Lambda$  is a diagonal matrix with positive diagonal components. Provide an expression of  $\hat{\beta}$  as a function of  $U$ ,  $D$ ,  $V$ ,  $\Lambda$  and  $Y$ .

In the proposed setting,

$$\hat{\beta} = (X^\top X + \Delta)^{-1} X^\top Y .$$

Let  $X = UDV^\top$  be a singular value decomposition of  $X$  and choose  $\Delta = V\Lambda V^\top$ . Then,

$$\begin{aligned}\hat{\beta} &= ((UDV^\top)^\top UDV^\top + V\Lambda V^\top)^{-1} (UDV^\top)^\top Y \\ &= (VD^\top U^\top UDV^\top + V\Lambda V^\top)^{-1} VD^\top U^\top Y \\ &= V (D^\top D + \Lambda)^{-1} D^\top U^\top Y .\end{aligned}$$

Contrary to the classical Ridge estimator, this estimator shrinks values of  $\beta$  with a different penalty for each component thanks to the matrix  $\Lambda$ .
